

Press release

20 September 2018

First patient included into ISR's Phase IIa HIV study

As previously announced, ISR has a Phase IIa study of HIV-infected patients on anti-retroviral therapy (ART), where patients will be randomized to receive ART with the addition of GnRH agonist (ISR048), or ART alone. The first patient is now enrolled.

ISR's Phase IIa clinical study, ISR-003, is conducted at the Karolinska University Hospital Huddinge and at the South Hospital in Stockholm, SÖS. The study is composed of two arms with a total of 26+26 patients to be randomized into ART+ISR048 or to ART alone in the control group. Patients will be treated for 3 months and then followed for an additional 3 months with the major readout HIV DNA reservoirs. The study is expected to be ending in Q2 2019.

"We are excited to have started enrolment of patients. The study is unique, where ISR048s capacity to eradicate HIV virus carrying cells will be evaluated", comments Ola Winqvist, CEO of ISR.
